

Daffodil International University
Faculty of Science & Information Technology
Department of Software Engineering
Final Examination, Summer 2026
Course Code: PHY 101 ; Course Title: Physics-I
Sections & Teachers: A-D(SH), E-G(RH).

RIA

Time: 2 Hrs
Marks: 40

Answer ALL Questions

[The figures in the right margin indicate the full marks and corresponding course outcomes.
All portions of each question must be answered sequentially.]

1.	a.	Describe the following terms: <i>✓</i>i. Nuclear fission in the Rooppur nuclear power plant <i>✓</i>ii. Photoelectric effect	5+5	CLO1, C1
2.	a.	Explain how attosecond LASER pulses can be used to study electron motion in a solar cell and how this knowledge may help improve its efficiency.	5	CLO2, C2
	b.	When sunlight passes through two tiny holes or gaps, we see light and dark lines on the wall. Estimate the intensity of the bright and dark fringes formed in <u>Young's double-slit</u> experiment.	5	
	c.	Elaborate with a supporting diagram how <u>Brewster's angle</u> , <u>Malus's law</u> , and <u>specific rotation</u> relate to light behavior, and compare how their applications differ from the light control mechanisms used in polaroid sunglasses.	5	
3.	a.	In an interference experiment using two narrow slits illuminated by a monochromatic light source, the separation between the centers of two consecutive bright fringes observed on a screen is found to be <u>0.55 mm</u> . The screen is placed <u>65 cm</u> away from the slits. The light used has a frequency of 6.2×10^{14} Hz. <i>✓</i>i. Calculate the separation between the slit. <i>✓</i>ii. If the slit separation is now doubled while keeping the wavelength and screen distance unchanged, compute the new fringe width. <i>✓</i>iii. Determine the position of the 4th bright fringe in both the original and the modified setup, and compare the two results. <i>✓</i>iv. Predict the total number of bright fringes that can be observed within a 12 mm width of the screen, centered on the central maximum.	7.5	CLO3, C3
	b.	A beam of light of wavelength 2.8×10^{-7} m is incident on a metallic plate of Zinc. The stopping potential is found to be <u>3.1 V</u> . <i>✓</i>i. Calculate the <u>maximum velocity</u> of photo electron in both Joules and eV. <i>✓</i>ii. Calculate the value of <u>work function</u> and <u>threshold frequency</u>. <i>✓</i>iii. If the <u>wavelength</u> of incident light is modified to 3.2×10^{-7} m, predict the new stopping potential and justify whether photoemission will still occur.	7.5
